# On simple ideal hyperbolic Coxeter polytopes 

A. Felikson, P. Tumarkin

## Introduction

Let $\mathbb{H}^{n}$ be the $n$-dimensional hyperbolic space and let $P$ be a simple polytope in $\mathbb{H}^{n} . P$ is called an ideal polytope if all vertices of $P$ belong to the boundary of $\mathbb{H}^{n} . P$ is called a Coxeter polytope if all dihedral angles of $P$ are submultiples of $\pi$.

There is no complete classification of hyperbolic Coxeter polytopes. In [6] Vinberg proved that there are no compact hyperbolic Coxeter polytopes in $\mathbb{H}^{n}$ when $n \geq 30$. Prokhorov [5] and Khovanskij [3] proved that there are no Coxeter polytopes of finite volume in $\mathbb{H}^{n}$ for $n \geq 996$. Examples of bounded Coxeter polytopes are known only for $n \leq 8$, and examples of finite volume non-compact Coxeter polytopes are known only for $n \leq 19$ [8] and $n=21$ [1].

In this paper, we prove that no simple ideal Coxeter polytope exists in $H^{n}$ when $n>8$.

The authors are grateful to the Max-Planck Institute for Mathematics in Bonn for hospitality and excellent research conditions.

## 1 Preliminaries

### 1.1 Coxeter diagrams

It is convenient to describe Coxeter polytopes in terms of Coxeter diagrams.
A Coxeter diagram is one-dimensional simplicial complex with weighted edges, where weights are either of the type $\cos \frac{\pi}{m}$ for some integer $m \geq 3$ or positive real numbers no less than one. We can draw edges of Coxeter diagram by the following way:
if the weight equals $\cos \frac{\pi}{m}$ then the nodes are joined by either $(m-2)$-fold edge or simple edge labeled by $m$;
if the weight equals one then the nodes are joined by a bold edge;
if the weight is greater than one then the nodes are joined by a dotted edge labeled by its weight.

A subdiagram of Coxeter diagram is a subcomplex that can be obtained by deleting several nodes and all edges that are incident to these nodes.

Let $\Sigma$ be a diagram with $d$ nodes $u_{1}, \ldots, u_{d}$. Define a symmetrical $d \times d$ matrix $G r(\Sigma)$ by the following way: $g_{i i}=1$; if two nodes $u_{i}$ and $u_{j}$ are adjacent then $g_{i j}$ equals negative weight of the edge $u_{i} u_{j}$; if two nodes $u_{i}$ and $u_{j}$ are not adjacent then $g_{i j}$ equals zero.

A Coxeter diagram $\Sigma(P)$ of Coxeter polytope $P$ is a Coxeter diagram whose matrix $\operatorname{Gr}(\Sigma)$ coincides with Gram matrix of $P$. In other words, nodes of Coxeter diagram correspond to facets of $P$. Two nodes are joined by either ( $m-2$ )-fold edge or $m$-labeled edge if the corresponding dihedral angle equals $\frac{\pi}{m}$. If the corresponding facets are parallel the nodes are joined by a bold edge, and if they diverge then the nodes are joined by a dotted edge.

By signature and rank of diagram $\Sigma$ we mean the signature and the rank of the matrix $G r(\Sigma)$.

A Coxeter diagram $\Sigma$ is called elliptic if the matrix $\operatorname{Gr}(\Sigma)$ is positively defined. A connected Coxeter diagram $\Sigma$ is called parabolic if the matrix $\operatorname{Gr}(\Sigma)$ is degenerated, and any subdiagram of $\Sigma$ is elliptic. Elliptic and connected parabolic diagrams are exactly Coxeter diagrams of spherical and Euclidean Coxeter simplices respectively. They were classified by Coxeter [2]. The complete list of elliptic and connected parabolic diagrams is represented in Table 1.

A non-connected diagram is called parabolic if it is a disjoint union of connected parabolic diagrams. A diagram is called indefinite if it contains at least one connected component that is neither elliptic nor parabolic.

Let $f$ be a $k$-dimensional face of $P$ (by abuse of notation we write $f$ is $a$ $k$-face of $P$ ). If $P$ is a simple $n$-dimensional polytope then $\alpha$ is an intersection of exactly $n-k$ facets. Let $f_{1}, \ldots, f_{n-k}$ be the facets containing $f$ and let $v_{1}, \ldots, v_{n-k}$ be the corresponding nodes of $\Sigma(P)$. Let $\Sigma_{f}$ be a subdiagram of $\Sigma(P)$ with nodes $v_{1}, \ldots, v_{n-k}$. We say that $\Sigma_{f}$ is the diagram of the face $f$.

The following properties of $\Sigma(P)$ and $\Sigma_{f}$ are proved in [7].

- [cor. of Th. 2.1] the signature of $G r(\Sigma(P))$ equals $(n, 1)$;
- [cor. of Th. 3.1] if a $k$-face $f$ is not an ideal vertex of $P$ (i.e. $f$ is not a point at the boundary of $\mathbb{H}^{n}$ ), then $\Sigma_{f}$ is an elliptic diagram of rank $n-k$;
- [cor. of Th. 3.2] if $f$ is an ideal vertex of $P$ then $\Sigma_{f}$ is a parabolic diagram of rank $n-1$; if $f$ is a simple ideal vertex of $P$ then $\Sigma_{f}$ is connected;
- [cor. of Th. 3.1 and Th. 3.2] any elliptic subdiagram of $\Sigma(P)$ corresponds to a face of $P$; any parabolic subdiagram of $\Sigma(P)$ is a subdiagram of the diagram of a unique ideal vertex of $P$.

As a corollary, for simple ideal Coxeter polytope $P \subset \mathbb{H}^{n}$ we obtain:
(I) Any two non-intersecting indefinite subdiagrams of $\Sigma(P)$ are joined in $\Sigma(P)$.
(II) Any elliptic subdiagram of $\Sigma(P)$ contains less than $n$ nodes;
(III) Any parabolic subdiagram of $\Sigma(P)$ is connected and contains exactly $n$ nodes;

Table 1: Connected elliptic and parabolic Coxeter diagrams are listed in left and right columns respectively.

| $\mathbf{A}_{\mathbf{n}}(n \geq 1)$ | $\bullet \bullet \cdots \bullet \bullet$ | $\begin{gathered} \widetilde{\mathbf{A}}_{\mathbf{1}} \\ \widetilde{\mathbf{A}}_{\mathbf{n}}(n \geq 2) \end{gathered}$ |  |
| :---: | :---: | :---: | :---: |
| $\begin{gathered} \mathbf{B}_{\mathbf{n}}=\mathbf{C}_{\mathbf{n}} \\ (n \geq 2) \end{gathered}$ | $\bullet \bullet \cdots \bullet \bullet$ | $\widetilde{\mathbf{B}}_{\mathbf{n}}(n \geq 3)$ | $\bullet \bullet \cdots \bullet$ |
|  |  | $\widetilde{\mathbf{C}}_{\mathbf{n}}(n \geq 2)$ | $\bullet$ |
| $\mathbf{D}_{\mathbf{n}}(n \geq 4)$ | $\bullet \bullet \cdots-\bullet$ | $\widetilde{\mathbf{D}}_{\mathbf{n}}(n \geq 4)$ | $\cdots$ |
| $\mathrm{G}_{2}$ | ¢ | $\widetilde{G}_{2}$ | - |
| $\mathrm{F}_{4}$ | $\bullet \bullet \bullet$ | $\widetilde{F}_{4}$ |  |
| $\mathrm{E}_{6}$ | $\ldots$ | $\widetilde{E}_{6}$ | $\cdots \bullet \bullet$ |
| $\mathrm{E}_{7}$ | $\bullet \bullet \cdot$ | $\widetilde{E}_{7}$ | $\cdots \cdots \cdots$ |
| $\mathrm{E}_{8}$ | $\bullet \bullet \bullet \bullet \bullet \bullet$ | $\widetilde{E}_{8}$ | $\cdots \bullet \bullet \cdots$ |
| $\mathrm{H}_{3}$ | - |  |  |
| $\mathrm{H}_{4}$ | - $\bullet$ |  |  |

Note, that a connected parabolic diagram with more than 3 nodes contains neither bold nor $k$-fold edges for $k>2$. Hence, a Coxeter diagram of simple ideal Coxeter polytope in $\mathbb{H}^{n}, n>3$, contains only simple edges, 2-fold edges and dotted edges.

## Notation

Let $F$ be a $k$-face of $P$ and let $f_{1}, \ldots, f_{n-k}$ be the facets of $P$ containing $F$. Let $v_{1}, \ldots, v_{n-k}$ be the corresponding nodes of $\Sigma(P)$.

- We denote by $\Sigma_{F}$ the subdiagram of $\Sigma(P)$ spanned by $v_{1}, \ldots, v_{n-k}$.
- We also write $\Sigma_{F}=\left\langle v_{1}, \ldots, v_{n-k}\right\rangle$ and $\left.\Sigma_{F}=<v_{1}, \Theta\right\rangle$, where $\Theta=<$ $v_{2}, \ldots, v_{n-k}>$. We denote by $\Sigma \backslash\left\{v_{1}, \ldots, v_{m}\right\}$ the subdiagram of $\Sigma$ spanned by all nodes of $\Sigma$ different from $v_{1}, \ldots, v_{m}$.
- For elliptic and parabolic diagrams we use standard notation (see Table 1). For example, we write $\Sigma_{F}=\widetilde{A}_{n}$.
- Let $v$ and $u$ be two nodes of $\Sigma(P)$. We write
$[v, u]=0$ if $u$ and $v$ are disjoint in $\Sigma(P)$;
$[v, u]=1$ if $u$ and $v$ are joined by a simple edge;
$[v, u]=2$ if $u$ and $v$ are joined by a 2 -fold edge;
$[v, u]=\infty$ if $u$ and $v$ are joined by a dotted edge.

### 1.2 Nikulin's estimate

Let $P$ be an $n$-dimensional polytope. Denote by $\alpha_{i}, i=0,1, \ldots, n-1$, the number of $i$-faces of $P$. For a face $f$ of $P$ denote by $\alpha_{i}^{f}$ the number of $i$-faces of $f\left(\right.$ e.g. $\left.\alpha_{i}=\alpha_{i}^{P}\right)$. Denote by

$$
\alpha_{k}^{(i)}=\frac{1}{\alpha_{k}} \sum_{d i m f=k} \alpha_{i}^{f}
$$

the average number of $i$-faces of a $k$-face of $P$.
Proposition 1 (Nikulin [4]). For every simple convex bounded polytope $P$ in $\mathbb{R}^{n}$ for $i<k \leq[n / 2]$ the following estimate holds:

$$
\alpha_{k}^{(i)}<\binom{n-i}{n-k} \frac{\binom{[n / 2]}{i}+\binom{[(n+1) / 2]}{i}}{\binom{[n / 2]}{k}+\binom{[(n+1) / 2]}{k}}
$$

Using this theorem for 2 -faces ( $i=0$ and $k=2$ ), Vinberg proved that no compact Coxeter polytope exists in $\mathbb{H}^{n}, n \geq 30$.

In [3], Khovanskij proved that Nikulin's estimate holds for edge-simple polytopes (a polytope is called edge-simple if any edge is the intersection of exactly $n-1$ facets). This was used by Prokhorov [5] when he proved that no Coxeter polytope of finite volume exists in $\mathbb{H}^{n}$ for $n \geq 996$.

In this paper, we study simple ideal hyperbolic Coxeter polytopes. Any hyperbolic Coxeter polytope of finite volume is edge-simple (see [3]). Thus, we can use Nikulin's estimate. We consider the combinatorics of Coxeter diagrams of simple ideal hyperbolic Coxeter polytopes and prove that such a polytope has no triangular 2-faces and that the number of quadrilateral 2 -faces of such a polytope is relatively small. This falls into a contradiction with Nikulin's estimate in dimensions greater than 8.

## 2 Absence of triangular 2-faces and estimate for quadrilateral 2 -faces.

Let $P$ be a simple ideal Coxeter polytope in $\mathbb{H}^{n}$ and let $V$ be a vertex of $P$. Since $P$ is simple, the vertex $V$ is contained in exactly $n$ edges $V V_{i}, i=1, \ldots, n$. Denote by $v_{i}$ the node of $\Sigma_{V}$ such that $\Sigma_{V V_{i}}=\Sigma_{V} \backslash\left\{v_{i}\right\}$. Denote by $u_{i}$ the node of $\Sigma(P)$ such that $\Sigma_{V_{i}}=\left\langle u_{i}, \Sigma_{V V_{i}}\right\rangle$.

Now, starting from the diagram $\Sigma_{V}$, we want to describe all possible diagrams $<v_{i}, u_{i}, \Sigma_{V V_{i}}>$. For example, suppose that $\Sigma_{V}=\widetilde{A}_{n-1}, n \neq 3,8,9$. Then $\Sigma_{V V_{i}}=\Sigma_{V} \backslash v_{i}=A_{n-1}$. It is easy to see, that if $n \neq 3,8,9$ then $\widetilde{A}_{n-1}$ is the only parabolic diagram with $n$ nodes containing a subdiagram $A_{n-1}$. Thus, $\Sigma_{V_{i}}=\widetilde{A}_{n-1}$. Note, that $\left[v_{i}, u_{i}\right] \neq 0$ and $\left[v_{i}, u_{i}\right] \neq 1$, otherwise $<v_{i}, u_{i}, \Sigma_{V V_{i}}>$ does not satisfy property (III). Hence, either $\left[v_{i}, u_{i}\right]=2$ or $\left[v_{i}, u_{i}\right]=\infty$, and the subdiagram $<v_{i}, u_{i}, \Sigma_{V V_{i}}>$ is one of two diagrams shown in Figure 1.

Figure 1: Two possibilities for $\left\langle v_{i}, u_{i}, \Sigma_{V V_{i}}\right\rangle$, if $\Sigma_{V}=\widetilde{A}_{n-1}, n \neq 3,8,9$.
Similarly, one can list all possible diagrams $<u_{i}, v_{i}, \Sigma_{V V_{i}}>$ for any other type of $\Sigma_{V}$. Recall that $\Sigma_{V}$ is one of the diagrams shown in the right column of Table 1. A case-by-case check using properties (I)-(III) shows the following:

Lemma 1. Suppose that $n>5$. In the notation above $\left[v_{i}, u_{i}\right] \neq 0$. If $\left[v_{i}, u_{i}\right]=1$ then, up to interchange of $v_{i}$ and $u_{i}$, the diagram $<v_{i}, u_{i}, \Sigma_{V V_{i}}>$ coincides with one of the diagrams shown in Figure 2.

Figure 2: Two possibilities for $\left\langle v_{i}, u_{i}, \Sigma_{V V_{i}}>\right.$ when $\left[v_{i}, u_{i}\right]=1$.
A node $v$ of a diagram $\Sigma$ is called a leaf of $\Sigma$ if $\Sigma$ contains exactly one node joined with $v$.

Lemma 2. Assume that $n>3$. Then for the diagram $<v_{i}, u_{i}, \Sigma_{V V_{i}}>$ the following property holds: if $v_{i}$ is a leaf of $\Sigma_{V}$ and $u_{i}$ is not a leaf of $\Sigma_{V_{i}}$ then $\Sigma_{V}=\widetilde{E}_{k}, \Sigma_{V_{i}}=\widetilde{A}_{k}$, where $k=7$ or 8 . In this case $<v_{i}, u_{i}, \Sigma_{V V_{i}}>$ is one of the diagrams shown in Figure 3.

Proof. Consider the subdiagram $\Sigma_{V V_{i}}$. Since $\Sigma_{V}=\left\langle\Sigma_{V V_{i}}, v_{i}>\right.$ and $v_{i}$ is a leaf of $\Sigma_{V}, \Sigma_{V V_{i}}$ is connected. Since $u_{i}$ is not a leaf of $\Sigma_{V_{i}}=\left\langle\Sigma_{V V_{i}}, u_{i}\right\rangle$, there are at least two edges joining $u_{i}$ with $\Sigma_{V V_{i}}$. Hence, $\Sigma_{V_{i}}$ contains a cycle. Combined with (III), this implies that $\Sigma_{V_{i}}=\widetilde{A}_{k}$. Hence, $\Sigma_{V V_{i}}=A_{k}$. The only parabolic diagrams with $k+1$ nodes containing a subdiagram $A_{k}$ are $\widetilde{A}_{k}, \widetilde{G}_{2}, \widetilde{E}_{7}$ and $\widetilde{E}_{8}$. Since $n>3$ and $\Sigma_{V}$ has at least one leaf $v_{i}, \Sigma_{V}=\widetilde{E}_{7}$ or $\widetilde{E}_{8}$.

We are left to show that $\left[v_{i}, u_{i}\right]=2$ or $\left[v_{i}, u_{i}\right]=\infty$. This follows from Lemma 1.

Figure 3: Possibilities for $<v_{i}, u_{i}, \Sigma_{V V_{i}}>$ when $v_{i}$ is a leaf of $\Sigma_{V}$ and $u_{i}$ is not a leaf of $\Sigma_{V_{i}}$

Lemma 3. Let $P$ be a simple ideal Coxeter polytope in $\mathbb{H}^{n}, n>5$. Then $P$ has no triangular 2-faces.

Proof. Suppose that $U V W$ is a triangular 2-face of $P$. Then there are exactly $n+1$ facets of $P$ containing at least one of the points $U, V$ and $W$. The whole triangle $U V W$ is contained in exactly $n-2$ of these facets. Since $P$ is simple, for each edge of $U V W$ there exists a unique facet containing the edge and not containing $U V W$. Denote these facets by $\bar{u}, \bar{v}$ and $\bar{w}$ for the edges $V W, U W$ and $U V$ respectively. Denote by $u, v$ and $w$ the nodes of $\Sigma(P)$ corresponding to $\bar{u}, \bar{v}$ and $\bar{w}$ respectively. Then $\Sigma_{U}=\left\langle v, w, \Sigma_{U V W}\right\rangle, \Sigma_{V}=\left\langle u, w, \Sigma_{U V W}\right\rangle$ and $\Sigma_{W}=\left\langle u, v, \Sigma_{U V W}\right\rangle$ (see Figure 4a). In particular, (III) implies that all these diagrams are parabolic.

Consider the edge of $\Sigma_{W}$ joining $u$ and $v$. By Lemma 1 , either $[u, v]=1$ or $[u, v]=2$ or $[u, v]=\infty$.

Figure 4: Notation for a triange (a) and for a quadrilateral (b).

Suppose that $[u, v]=\infty$. Then $\Sigma_{W}=\left\langle u, v, \Sigma_{U V W}\right\rangle$ contains a dotted edge, in contradiction to the fact that $\Sigma_{W}$ is parabolic. Thus, $[u, v] \neq \infty$ and, similarly, $[v, w] \neq \infty$ and $[u, w] \neq \infty$.

Suppose that $u$ is a leaf of $\Sigma_{V}$ and $v$ is not a leaf of $\Sigma_{U}$. Then Lemma 2 shows that $\left\langle w, \Sigma_{W}\right\rangle=\left\langle u, v, w, \Sigma_{U V W}\right\rangle$ is one of the diagrams shown in Figure 3. No of these diagrams contains a node $w \neq u, v$, such that $\left\langle u, v, \Sigma_{U V W}\right\rangle$ is parabolic. Thus, no of these diagrams corresponds to a triangle, and we may assume that either both $u$ and $v$ are the leaves of $\Sigma_{V}$ and $\Sigma_{U}$ respectively or none of them is.

Suppose that $[u, v]=2$. It follows from Table 1 and the assumption $n>5$ that either $u$ or $v$ is a leaf of $\Sigma_{W}$. Without loss of generality we can assume that $u$ is a leaf. Then it is easy to see that we have one of the diagrams shown in Figure 5. Consider the case shown in Figure 5a. Since $[u, w] \neq \infty$, the diagram $<u, w, \Sigma_{U V W}>=\Sigma_{V}$ is elliptic, that is impossible by (II). Consider the case shown in Figure 5b. If $[u, w]=1$ then $\left\langle u, w, \Sigma_{U V W}\right\rangle=\Sigma_{V}$ is elliptic, that is impossible. If $[u, w]=2$ then $\langle u, v, w\rangle$ is a parabolic diagram with only three nodes in contradiction to (III).

Figure 5: Possibilities for the case $[u, v]=2$.
Suppose that $[u, v]=1$. By Lemma $1, \Sigma_{W}=\left\langle u, v, \Sigma_{U V}\right\rangle$ coincides with one of the diagrams shown in Figure 2 (up to interchange of $u$ and $v$ ). It is easy to see that $\Sigma_{U V}$ contains no node $w \neq u, v$ such that $<u, v, \Sigma_{U V} \backslash w>$ is a parabolic diagram. Note that $\Sigma_{U V}=<w, \Sigma_{U V W}>$ and $<u, v, \Sigma_{U V} \backslash w>=<$ $u, v, \Sigma_{U V W}>=\Sigma_{W}$. Thus, we have no parabolic diagram $\Sigma_{W}$, so $[u, v] \neq 1$.

By Lemma 1, the case $[u, v]=0$ is also impossible. There are no more possibilities for $[u, v]$. Hence, no diagram $\Sigma_{U V W}$ can be constructed, and $P$ contains no triangular faces.

Note that an ideal Coxeter polytope in $\mathbb{H}^{5}$ may have a triangular 2-face. For example, the Coxeter diagram shown in Figure 6 determines a 5-dimensional ideal Coxeter simplex. All 2 -faces of any simplex are triangles.

Figure 6: This diagram determines a 5-dimensional ideal Coxeter simplex.

Lemma 4. Let $V$ be a vertex of simple ideal Coxeter polytope $P$ in $\mathbb{H}^{n}, n>9$. Then $V$ belongs to at most $n+3$ quadrilateral 2-faces.
Proof. Let $q$ be a quadrilateral 2-face with vertices $V, V_{i}, V_{j}$ and $V_{i j}$. The 2face $q$ belongs to $n-2$ facets, each edge of $q$ belongs to $n-1$ facets and each vertex belongs to $n$ facets. Denote by $\bar{v}_{i}, \bar{u}_{i}, \bar{v}_{j}$ and $\bar{u}_{j}$ the facets not containing $q$ and containing the edges $V V_{j}, V_{i} V_{i j}, V V_{i}$ and $V_{j} V_{i j}$ respectively (see Figure 4 b ). Denote by $v_{i}, u_{i}, v_{j}$ and $u_{j}$ the nodes of $\Sigma(P)$ corresponding to the facets $\bar{v}_{i}, \bar{u}_{i}, \bar{v}_{j}$ and $\bar{u}_{j}$ respectively.

Then $\left.\left.\left.\Sigma_{V}=<v_{i}, v_{j}, \Sigma_{q}\right\rangle, \Sigma_{V_{i}}=<v_{j}, u_{i}, \Sigma_{q}\right\rangle, \Sigma_{V_{j}}=<v_{i}, u_{j}, \Sigma_{q}\right\rangle$, and $\left.\Sigma_{V_{i j}}=<u_{i}, u_{j}, \Sigma_{q}\right\rangle$. See Figure 7 for an example of a quadrilateral.

Figure 7: Example of a quadrilateral
Suppose that $\Sigma_{V}=\widetilde{A}_{n-1}$ and $v_{i}$ and $v_{j}$ are disjoint in $\Sigma_{V}$. Since $n>8$, each of the vertices $V_{i}, V_{j}, V_{i j}$ are of the type $\widetilde{A}_{n-1}$. Consider $<v_{i}, u_{i}, \Sigma_{V V_{i}}>$.

By (III), either $\left[v_{i}, u_{i}\right]=\infty$ or $\left[v_{i}, u_{i}\right]=2$ (cf. Figure 1). The same statement holds for $\left[v_{j}, u_{j}\right]$. Since $\Sigma_{V_{i j}}$ is a parabolic diagram $\widetilde{A}_{n-1}$, we have $\left[u_{i}, u_{j}\right]=0$ (see Figure 8). Then $\Sigma(P)$ contains two disjoint indefinite subdiagrams $v_{i} u_{i} w_{i}$ and $v_{j} u_{j} w_{j}$. Thus, any quadrilateral containing $V$ corresponds to a pair of neighbouring nodes of $\Sigma_{V}$, and $V$ belongs to at most $n$ quadrilaterals.

Figure 8: $v_{i} u_{i} w_{i}$ and $v_{j} u_{j} w_{j}$ are disjoint indefinite subdiagrams. In this diagrams $k_{i}, k_{j}=2$ or $\infty$.

From now on we assume that $\Sigma_{V} \neq \widetilde{A}_{n-1}$. Since $n>9, \Sigma_{V}=\widetilde{B}_{n-1}, \widetilde{C}_{n-1}$ or $\widetilde{D}_{n-1}$. Define a distance $\rho(u, w)$ between two nodes $u$ and $w$ of connected graph as the number of edges in the shortest path connecting $u$ and $w$.

Let $x$ be a leaf of $\Sigma_{V}$. Denote by $\Sigma_{V}^{(5)}(x)$ a connected subdiagram of $\Sigma_{V}$ spanned by five nodes closest to $x$ in $\Sigma_{V}$ (i.e., if $v_{k} \in \Sigma_{V}^{(5)}(x)$ and $v_{l} \notin \Sigma_{V}^{(5)}(x)$ then $\rho\left(x, v_{k}\right) \leq \rho\left(x, v_{l}\right)$. Note that for $\Sigma_{V}=\widetilde{B}_{n-1}, \widetilde{C}_{n-1}$ and $\widetilde{D}_{n-1}$ when $n \geq 9$ the diagram $\Sigma_{V}^{(5)}(x)$ is well-defined for any leaf $x$ of $\Sigma_{V}$.

Denote by $L\left(\Sigma_{V}\right)$ the set of leaves of $\Sigma_{V}$. Define

$$
\Sigma_{V}^{(5)}=\bigcup_{x_{i} \in L\left(\Sigma_{V}\right)} \Sigma_{V}^{(5)}\left(x_{i}\right)
$$

(see Fig. 9). It is easy to see that if $n>10$ then $\Sigma_{V}^{(5)}$ consists of two connected components.

Figure 9: Subdiagram $\Sigma_{V}^{(5)}$ for $\Sigma_{V}=\widetilde{B}_{12}$.
Suppose that $v_{i}$ and $v_{j}$ do not belong to the same connected component of $\Sigma_{V}^{(5)}\left(v_{i}\right.$ or $v_{j}$ may lie in $\left.\Sigma_{V} \backslash \Sigma_{V}^{(5)}\right)$. By the same reason as in the case $\Sigma_{V}=\widetilde{A}_{n-1}$, nodes $v_{i}$ and $v_{j}$ are neighbours in $\Sigma_{V}$.

Suppose that $v_{i}$ and $v_{j}$ belong to the same connected component of $\Sigma_{V}^{(5)}$. Suppose that $v_{i}$ and $v_{j}$ are disjoint. A straightforward check of possibilites with
use of properties (I)-(III) shows that if $\Sigma_{q}$ is the diagram of a quadrilateral 2face, then the connected component of $\Sigma_{V}^{(5)}$ is one of the following configurations (up to interchange of $v_{i}$ and $v_{j}$ ):

Hence, the quadrilaterals containing $V$ are encoded either by one of $n-1$ pair of neighbouring nodes of $\Sigma_{V}$ or by one of two pairs of nodes for each of two connected components of $\Sigma_{V}^{(5)}$. Thus, the number of quadrilaterals containing $A$ is less than or equal to $2+2+(n-1)=n+3$.

Lemma 5. Let $A$ be a vertex of a simple ideal Coxeter polytope $P$ in $\mathbb{H}^{9}$. Then A belongs to at most 15 quadrilateral 2-faces.
Proof. The existence of $\Sigma_{V}=\widetilde{E}_{8}$ course a lot of possibilities for the diagram $<v, v_{i}, \Sigma_{V V_{i}}>$. This leads to a large number of different diagrams $<v, v_{i}, \Sigma_{q}>$. To observe all these possibilities we use a case-by-case check organized as follows:
Step 1. We consider the cases $\Sigma_{V}=\widetilde{A}_{8}, \widetilde{B}_{8}, \widetilde{C}_{8}, \widetilde{D}_{8}$ and $\widetilde{E}_{8}$ separately.
Step 2. For each node $v_{i}, i=1, \ldots, 9$, of $\Sigma_{V}$ we list all possible diagrams $<$ $v_{i}, u_{i}, \Sigma_{V V_{i}}>$ such that $<u_{i}, \Sigma_{V V_{i}}>$ is parabolic and $<v_{i}, u_{i}, \Sigma_{V V_{i}}>$ satisfies properties (I)-(III). We call such a diagram $<v_{i}, u_{i}, \Sigma_{V V_{i}}>$ an edge-pattern. Clearly, any edge incident to $V$ corresponds to some edgepattern $<v_{i}, u_{i}, \Sigma_{V V_{i}}>$.
Some nodes $v_{i}$ of $\Sigma_{V}$ may admit several edge-patterns $\left.<v_{i}, u_{i}, \Sigma_{V V_{i}}\right\rangle$ (up to 8 edge-patterns for one of the nodes of $\widetilde{E}_{8}$ ). Denote the edge-patterns by $\left(v_{i}, u_{i}\right)_{r}, r=1, \ldots, k_{i}$, where $k_{i}$ is the number of patterns for the node $v_{i}$ of $\Sigma_{V}$.

Step 3. For each edge-pattern $\left(v_{i}, u_{i}\right)_{r}$ we consider all edge-patterns $\left(v_{j}, u_{j}\right)_{s}, j \neq$ i. We list all cases when $v_{i}, u_{i}, v_{j}, u_{j}$ correspond to the facets of some quadrilateral 2-face $q$ (where $\Sigma_{q}=\Sigma_{V} \backslash\left\{v_{i}, v_{j}\right\}$ ).

Step 4. For each node $v_{i}, 1 \leq i \leq 9$, choose an edge-pattern $\left(v_{i}, u_{i}\right)_{r_{i}}$. Then compute the total number $Q\left(r_{1}, \ldots, r_{9}\right)$ of quadrilaterals determined by $\left(v_{i}, u_{i}\right)_{r_{i}}$ and $\left(v_{j}, u_{j}\right)_{r_{j}}$ for $1 \leq i<j \leq 9$.

Step 5. Denote by $Q\left(\Sigma_{V}\right)$ the maximal value of $Q\left(r_{1}, \ldots, r_{9}\right)$ for all $r_{1}, \ldots, r_{9}$. It turns out that

$$
\begin{aligned}
& Q\left(\widetilde{A}_{8}\right)=15, \\
& Q\left(\widetilde{B}_{8}\right)=14, \\
& Q\left(\widetilde{C}_{8}\right)=12,
\end{aligned}
$$

$$
\begin{aligned}
& Q\left(\widetilde{D}_{8}\right)=15, \\
& Q\left(\widetilde{E}_{8}\right)=14 .
\end{aligned}
$$

Thus, for any type of $\Sigma_{V}$ we obtain that $V$ belongs to at most 15 quadrilateral 2-facets.

Remark. At step 4 of the algorithm above one should check a huge number of possibilities (more than 15000 cases for $\widetilde{E}_{8}$ ). This was done by computer.

## 3 Absence of simple ideal Coxeter polytopes in large dimensions.

Recall that $\alpha_{i}$ denotes the number of $i$-faces of a polytope $P$ and $\alpha_{k}^{(i)}$ denotes the average number of $i$-faces of $k$-face of $P$.

We will need the following lemma:
Lemma 6. Let $P$ be an n-dimensional simple polytope and let $l$ be the number of vertices of $P$. Then

$$
\begin{equation*}
\frac{l}{\alpha_{2}}=\frac{2}{n(n-1)} \alpha_{2}^{(1)} \tag{1}
\end{equation*}
$$

Proof. Denote by $m_{i}$ the number of $i$-angular 2-faces of $P$. Let us compute the total number $N$ of vertices of 2-faces. Clearly, $N=\sum_{i \geq 3} i \cdot m_{i}$. From the other hand, each pair of edges incident to one vertex of simple polytope determines a 2 -face of the polytope. Thus, $N=l \frac{n(n-1)}{2}$, and we obtain the following equality

$$
\begin{equation*}
l \frac{n(n-1)}{2}=\sum_{i \geq 3} i \cdot m_{i} \tag{2}
\end{equation*}
$$

By definition,

$$
\begin{equation*}
\alpha_{2}^{(1)}=\frac{\sum_{i \geq 3} i \cdot m_{i}}{\alpha_{2}} . \tag{3}
\end{equation*}
$$

Combining (2) and (3), we obtain

$$
\frac{l}{\alpha_{2}}=\frac{2}{n(n-1)} \frac{\sum_{i \geq 3} i \cdot m_{i}}{\alpha_{2}}=\frac{2}{n(n-1)} \alpha_{2}^{(1)}
$$

Theorem 1. There is no simple ideal Coxeter polytope in $\mathbb{H}^{n}$ for $n \geq 9$.

Proof. We use the notation from Lemma 6. Recall, that $\alpha_{2}=\sum_{i \geq 3} m_{i}$. By Lemma 3, $m_{3}=0$. Using (3), we have

$$
\begin{equation*}
\alpha_{2}^{(1)} \geq \frac{1}{\alpha_{2}}\left(4 m_{4}+5 \sum_{i \geq 5} m_{i}\right)=\frac{1}{\alpha_{2}}\left(5 \sum_{i \geq 4} m_{i}-m_{4}\right)=5-\frac{m_{4}}{\alpha_{2}} \tag{4}
\end{equation*}
$$

Consider Nikulin's estimate for $\alpha_{2}^{(1)}$ :

$$
\begin{equation*}
\alpha_{2}^{(1)}<\binom{n-1}{n-2} \frac{\binom{[n / 2]}{1}+\binom{[(n+1) / 2]}{1}}{\binom{[n / 2]}{2}+\binom{[(n+1) / 2]}{2}}=4 \frac{n-1+\varepsilon}{n-2+\varepsilon} \tag{5}
\end{equation*}
$$

where $\varepsilon=0$ if $n$ is even and $\varepsilon=1$ if $n$ is odd.
Combining (4) with (5), we obtain

$$
\begin{equation*}
5-\frac{m_{4}}{\alpha_{2}} \leq \alpha_{2}^{(1)}<4 \frac{n-1+\varepsilon}{n-2+\varepsilon} \tag{6}
\end{equation*}
$$

Denote by $l$ the number of vertices of $P$. Denote by $N_{4}$ the total number of vertices of quadrilateral 2-faces. Clearly, $N_{4}=4 m_{4}$. By Lemmas 4 and 5 each of $l$ vertices is incident to at most $n+6$ quadrilaterals. Thus, $N_{4} \leq l(n+6)$ and we have $4 m_{4} \leq l(n+6)$. In view of (1) and (5), we have

$$
\begin{align*}
\frac{m_{4}}{\alpha_{2}} \leq \frac{1}{4} \frac{l(n+6)}{\alpha_{2}} & =\frac{n+6}{4} \frac{2}{n(n-1)} \alpha_{2}^{(1)}< \\
& <\frac{n+6}{2 n(n-1)} \frac{4(n-1+\varepsilon)}{(n-2+\varepsilon)}=2 \frac{n+6}{n(n-1)} \frac{(n-1+\varepsilon)}{(n-2+\varepsilon)} \tag{7}
\end{align*}
$$

Combining (6) and (7), we obtain

$$
5-\frac{4(n-1+\varepsilon)}{(n-2+\varepsilon)}<\frac{m_{4}}{\alpha_{2}}<2 \frac{n+6}{n(n-1)} \frac{(n-1+\varepsilon)}{(n-2+\varepsilon)} .
$$

This implies

$$
(n-6+\varepsilon) n(n-1)<2(n+6)(n-1+\varepsilon)
$$

This is equivalent to $n^{2}-8 n-12<0$ if $n$ is even and to $n^{2}-8 n-7<0$ if $n$ is odd. The first inequality has no solutions for $n \geq 10$, and the second one has no solutions for $n \geq 9$. So, the theorem is proved.
